5 SYSTEM AND METHOD FOR PATTERN IDENTIFICATION

BACKGROUND OF THE INVENTION

1. Field of the Invention

10 This invention relates to machine vision, and more particularly, to a system and method
for pattern identification.

2. Description of the Related Art

15 Automated manufacturing processes often rely on machine vision systems to identify and
locate parts that are being assembled. This allows a machine, such as a robot, to interact with
(e.g., pick up) the individual parts using pattern recognition. For example, the pattern could be
an image of the part, such as an image of a keypad of a cellular phone unit that is to be assembled
in a housing. A linear pattern, such as a cross hair, may also be used to aid in precision
alignment.

20 Various methods of machine vision positioning are currently practiced, including
variations based on the general Hough transform and variations based on correlation (template
matching). Correlation may use binary exclusive-OR correlation and, more recently, gray-scale
normalized correlation. One common element of these systems is that they require, as input, an
image template of the part whose pattern is being located.

25 The Hough transform, however, is inefficient when the part to be located is subject to
rotation because, generally, multiple analyses must be performed using different potential angles
of rotation. Specifically, for each possible angle of rotation, the Hough transform generally
requires a separate reference table. Accordingly, if a user wants to have full rotation search
capability at ten degree increments in angles of rotation, then the Hough transform would require

a minimum of thirty-six tables, and then sequential searches would have to be performed on each table. Because such a analysis is computationally demanding, the search time is significantly increased.

SUMMARY OF THE INVENTION

Therefore, a need has arisen for a system and method for pattern identification that overcomes these and other shortcomings of the related art.

According to one embodiment of the present invention, a method for locating a pattern is disclosed. The method includes the steps of (1) providing a pattern image corresponding to the pattern to be located; (2) extracting a pattern contour from the pattern image; (3) generating vector information for the pattern contours, relative to a reference point; (4) creating a reference table for storing the vector information, the reference tables corresponding to the pattern contour; (5) providing a scene image, which will be searched for the pattern; (6) extracting a scene contour from the scene image; (7) generating vector information for the scene contours; and (8) determining whether the pattern has been located within the scene image using the reference table and the vector information for the scene contour, and if so, identifying a location of the pattern within the scene image and an angle of rotation of the pattern within the scene image.

In another embodiment, a method for pattern recognition comprises the following steps: (1) extracting pattern vector information from at least one pattern image, each pattern image having a pattern reference point; (2) creating a reference table containing the pattern vector information for each of the at least one pattern image; (3) extracting scene contour information from a scene image; (4) calculating a potential reference point based on the scene contour information and the reference table; (5) matching the potential reference point with one of the at least one pattern reference points; and (6) identifying a pattern image corresponding to the matching pattern reference point.

In still another embodiment, a system for pattern identification is disclosed. The system

includes a first image capture device that captures a pattern image which includes an image of a pattern; a second image capture device that captures a scene image to be searched for the pattern; a processor processing the images, which includes means for extracting at least one pattern contour from the pattern image; means for generating vector information for each of said at least one pattern contours, relative to a reference point; means for creating at least one reference table for storing vector information, each of said at least one reference tables corresponding to at least one pattern contour; a means for extracting at least one scene contour from a scene image; means for generating vector information for each of said at least one scene contours; and means for locating the pattern image within the scene image using the at least one reference tables and the vector information for the at least one scene contours.

BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the present invention, the objects and advantages thereof, reference is now made to the following descriptions taken in connection with the accompanying drawings in which:

Fig. 1 depicts an example of a pattern;

Fig. 2 illustrates an illustration of a contour according to one embodiment of the present invention;

Fig. 3 illustrates a flowchart of a method for pattern identification according to one embodiment of the present invention;

Fig. 4 illustrates a flowchart of a training process;

Fig. 5 illustrates a flowchart of a search process;

Fig. 6a illustrates an example of a pattern (x, y) location image according to one embodiment of the present invention;

Fig. 6b illustrates an example of a pattern angle image according to one embodiment of the present invention;

Fig. 7 illustrates an example of a pattern image to be trained;

Fig. 8 illustrates the pattern image of Fig. 7 including index points, front and back points, and stick vectors;

Fig. 9 illustrates a graphical plot of the points identified in Fig. 8;

Fig. 10 illustrates scene image to be searched for the pattern shown in Fig. 7;

Fig. 11 illustrates a plot of the index points and front and back points of the scene image of Fig. 10; and

Fig. 12 illustrates an image of the accumulator for the scene image of Fig. 10.

DETAILED DESCRIPTION OF THE INVENTION

The preferred embodiment of the present invention and its advantages are best understood by referring to Figs. 1 through 12 of the drawings, like numerals being used for like and corresponding parts of the various drawings.

For convenience, the present invention will be described with the following convention, with reference to image 102 shown in Fig. 1. Image 102 may be a digital image of a part or an object. In the figure, image 102 is a digital image of a shutter speed selection knob for a camera. It may be desirable for a machine to determine the precise orientation of this part (such as its rotation) so that a machine may properly interact with this part during assembly.

Image 102 may include one or more patterns 103. In the figure, image 102 includes several patterns 103, including, for example, the outer cylindrical surface of the knob, the hollow interior of the knob, as well as the various numbers and letters on the knob indicating different shutter speeds.

Pattern 103 may also include at least one contour 104. In general, contour 104 may be thought of as being an ordered list of edge point coordinates that describe a boundary of a pattern, including both internal and external boundaries. In the figure, for example, contour 104 is indicated at the outer edge of the knob.

Generally, the present invention “trains” on image 102 so that the invention will know the pattern of the part for which the invention is looking. During the training process, the present invention is given, or creates, a “pattern image,” and the system trains on the pattern image. During the searching process, the present invention searches a “scene image” in an effort to locate the pattern that was used to train the system. So, when the term “pattern image” is used, this application is referring to the image used in training, and when the term “scene image” is used, this application is referring to the search process.

A brief discussion of the theory of the present invention is provided. Fig. 2 illustrates a contour that has been extracted, for example, from a pattern image during the training process. Referring to Fig. 2, contour 202 includes a plurality of contour points 204, which lie along contour 202. Index point 206 (located at (x_0, y_0)), which is a contour point, is selected, and two reference points, back point 208 (located at (x_1, y_1) , and “behind” index point 206 by a constant k) and front point 210 (located at (x_2, y_2) , and “in front of” index point 206 by a constant k (not shown)) are selected. Variable k controls the locality of the curvature measurement. In one embodiment, k represents the number of contour points that separate back point 208 from index point 206, which is the same as the number of contour points separating front point 210 from index point 206. A smaller value for k gives very local curvature measurements, while a larger value for k gives more global measurements.

In one embodiment, indices of front point 208 and back point 210 may be selected automatically. In general, they are separated from index of index point 206 by k (i.e., each is k data points away from index point 206). The index of front point 208 is smaller than the index of index point 206 by k , while the index of back point 210 is larger than the index of index point 206 by k . For example, if (x_0, y_0) is at index 100, then back point 208 is the point at index 90, and front point 210 is at index 110 (for $k=10$).

Generally, k is chosen based upon the severity of the curves in the pattern contours and based upon the number of contour points that are used to represent the contour. Generally, a

smaller k may be preferred, but k must not be too small. A k of 10 will work in most standard applications.

Stick vector 212, which is a vector that connects back point 208 and front point 210, has a direction representing the direction of “crawl;” that is, the direction from back point 208 to front point 210. Stick vector 212 has an angle of θ_0 relative to the horizontal axis.

In another embodiment, an additional back point (not shown) and an additional front point (not shown) may also be used. In general, these points may be indexed with a value greater than k . These points may be used to define an additional stick vector (not shown), which may provide additional information regarding contour 202.

Line 209 connects index point 206 and back point 208, while line 211 connects index point 206 and front point 210. Angle θ_2 represents the angle between stick 212 and line 211.

Algorithm reference point 214, located at (x_C, y_C) , may be selected by a user, or it may be the centroid of the pattern, as will be discussed in greater detail below.

A distance h represents a contour curvature measure for contour point 206. The distance h is the shortest distance from index point 206 to stick 212. For example, for an appropriate k value, a value of $h=0$ indicates that the stick is falling on a straight line.

Vector R may be constructed by drawing a vector from contour point 206 to algorithm reference point 214. This vector has magnitude of d , a direction pointing from contour point 206 to algorithm reference point 214, and angle θ_1 relative to the horizontal axis. Angle $\delta\theta$ is the angle between R and stick vector 212. Angle $\delta\theta$ may also be referred to as the “SR Angle.” Angle $\delta\theta$ is rotation invariant. This means that regardless of any rotation of contour 202 (or rotation of the part/object) relative to the horizontal axis, this angle is the same for a particular point on contour 202. Because angle $\delta\theta$ is rotation invariant, it is an ideal variable, as it reduces search time significantly. It also eliminates the need for a separate table for each angle of rotation.

Angle $\delta\theta_{\text{Gradient}}$ is the angle between gradient 216 and vector R. This may also be referred

to as the “GR Angle.” In general, $\delta\theta_{\text{Gradient}}$ determines the position of algorithm reference point 214 relative to stick vector 212 (i.e., (on what side of stick vector 212) so long as contour 202 is crawled on in the same direction when training and when searching. Crawling in the same direction may not happen in every image, due to disconnection or extra connection of a contour.

5 In general, the lengths and angles identified above may be determined by trigonometry, or by other higher-level mathematics.

With the convention and theory described above in mind, a flowchart of a method for pattern identification according to one embodiment of the present invention is provided in **Fig. 3**. First, in step 302, the system is “trained” on a pattern image. Referring to **Fig. 4**, a flowchart of the training process is provided. First, in step 402, pattern contours are extracted from the pattern image. In one embodiment, this may be achieved by detecting the levels of the edges on the pattern image, which computes the optimal value for the edge level (i.e., the edge strength) in order to filter out noise edge pixels. Other filters may be used as desired.

15 Pattern contours may be extracted from the pattern image, preferably after any conditioning. In one embodiment, an extraction engine, such as EdgeCrawler, developed by Imaging Technology, Inc., of Bedford, Massachusetts, may be used to extract the contours from the pattern image. The extraction engine may extract edge pixels by running a Gaussian filter followed by a Sobel transform. Non-maxima suppression may be performed on all edge points above the value of the level detected by the edge level detection. In another embodiment, a top-down crawler may be used to create a contour from the edges.

20 In another embodiment, the edges may be extracted by locating at least one edge of the pattern image of the scene image and recording a starting point for the edge. The edge is then “crawled” along; that is, each pixel along the edge is analyzed. As the pixels are analyzed, they may be extracted from the edge, and then may be filtered. A contour may then be created from the filtered and extracted pixels.

25 Next, in step 404, the extracted contours may be conditioned. This step helps to identify

and add undetected edge points, if any. In addition, aliased edge points may be removed. In one embodiment, each contour may be spatially filtered with a 5×1 filter. Of course, different filters may be used. Each contour may then be normalized to create a new set of contours in which the distance between any neighboring points is 1.0 (one) pixel. Raw contour points may have a spacing that varies between 1 and 1.41 pixels in distance, depending on the angle between points. The result of the contour conditioning stage is at least one pattern contour.

In step 406, an algorithm reference (x, y) position may be selected. Step 406 may be exercised before step 404, or even after step 408. In one embodiment, the reference point may be the centroid coordinate, or central moment, of the pattern contour(s). At the end of searching, the algorithm reference point may be translated back to user coordinates.

In step 408, the pattern contour may be optimized. This may be accomplished by setting levels based on the analysis of pattern contours, including the number of contour points, the curvature statistics of contour points, etc. These points may be used to determine the values of each parameter.

In step 410, a reference table is created. This may be performed simultaneously with step 408. This may be accomplished by analyzing every contour in the pattern contours, and for every point on the contour, extracting the contour curvature, h , the vector $R(r, \theta_1)$, the angle between the R vector and the stick vector $\delta\theta$, and the angle $\delta\theta_{\text{Gradient}}$. In one embodiment, these values may be grouped in a reference table according to their contour curvature h in order to decrease search time, and to better shape the peak shape in the pattern location image, discussed below.

An example of a reference table is provided below, wherein each rectangle may include data represented generically by variable. The fact that the identical variables are shown in the table is not intended to suggest that each measurement for the variables are identical.

$h = 0$	$h = 1$	$h = 2$	$h = 3$
r θ_1 $\delta\theta$ $\delta\theta_{\text{Gradient}}$	r θ_1 $\delta\theta$ $\delta\theta_{\text{Gradient}}$	r θ_1 $\delta\theta$ $\delta\theta_{\text{Gradient}}$	r θ_1 $\delta\theta$ $\delta\theta_{\text{Gradient}}$
r θ_1 $\delta\theta$ $\delta\theta_{\text{Gradient}}$	r θ_1 $\delta\theta$ $\delta\theta_{\text{Gradient}}$		r θ_1 $\delta\theta$ $\delta\theta_{\text{Gradient}}$
r θ_1 $\delta\theta$ $\delta\theta_{\text{Gradient}}$	r θ_1 $\delta\theta$ $\delta\theta_{\text{Gradient}}$		
r θ_1 $\delta\theta$ $\delta\theta_{\text{Gradient}}$			

Referring again to **Fig. 3**, in step 304, once the training is complete, the reference table and related information may be stored in a database. In one embodiment, the database may include a plurality of reference tables for different pattern images.

In step 306, a scene image is acquired. In one embodiment, the scene image may be acquired in real-time; in other embodiments, the scene image may be acquired from a database, or provided to the system from an outside source.

In step 308, the scene image is searched. Referring to **Fig. 5**, a flowchart of the search process is provided. In step 502, contours are extracted from the scene image. In one embodiment, contours may be extracted from the scene image in the same way that contours were extracted from the pattern image. Therefore, a detailed description of this step is omitted.

In step 504, the contours may be conditioned and/or normalized. In one embodiment, contours may be conditioned and/or normalized from the scene image in the same way that contours were conditioned and/or normalized from the pattern image. Therefore, a detailed description of this step is omitted.

In step 506, as the contour points are crawled, the values of h , θ_0 , and θ_{Gradient} for each

contour point are determined.

In step 508, the location of a potential reference point is computed from scene θ_0 (the angle between a scene stick and the horizontal axis) and $R(r, \delta\theta_1)$ of a cell in the table. In doing so, the scene contour curvature value, h , may be used to select a column of the table. A potential reference point for the scene pattern is calculated for each table cell in that column (all the points with the same contour curvature value h).

The potential reference point (x, y) is entered into a reference point accumulator which “counts” each instance of a potential reference point. In one embodiment, a pattern location image, in which the pixel value at the reference coordinates is incremented each time a calculation yields a reference point with that coordinate, is used as the accumulator. In other words, the “height” of a particular coordinate increases each time the particular coordinate is calculated as a potential reference point. In one embodiment, this step may be repeated for each of the scene contour points.

An example of a pattern location image is provided in **Fig. 6a**. In **Fig. 6a**, the tallest column reflects an accumulator that shows the greatest number of “hits,” and hence, the greater likelihood of a match.

Referring again to **Fig. 5**, in step 510, the angle of rotation of the pattern may be computed. This angle may be computed based upon the angle difference between θ_0 (stick vector angle) of scene point, and θ_0 in the table cell. This angle is also entered into an angle accumulator, which tallies each instance of an angle. In one embodiment, a pattern angle image in which the angle value is stored (stacked) at computed (x, y) coordinates may be used.

In another embodiment, the angle difference between θ_{Gradient} of the scene point, and θ_{Gradient} in the table cell may be used. In general, however, θ_0 may be more stable than θ_{Gradient} .

An example of a pattern angle image is provided in **Fig. 6b**.

Referring again to **Fig. 5**, in step 512, after all points are processed, the accumulator for the potential reference point is analyzed to determine the best potential reference point.

Next, in step 514, the angle of rotation is determined. In one embodiment, a clustering algorithm, may be used to determine the angle of rotation. The clustering algorithm may return a predetermined number of strong “peaks,” as well as smaller peaks near a strong peak. The clustering algorithm may average the peaks to return the most likely angle of rotation.

5 In step 516, edges may be verified. After the best potential reference point and rotation angle for the pattern are identified, the position of all edge points for the potential reference point (forming a potential pattern) may be translated into the coordinates of the scene. This may be done by moving a position of the potential pattern to the potential reference point, and then rotating the potential pattern using the angle returned by the search. Depending on the accuracy, 10 the two sets of edge points (edge points for the potential pattern, and edge points for the pattern) may overlap spatially. The movement and the rotation should cause the edges of the potential pattern and the pattern image to overlap. The verification procedure verifies that, for each model edge point, there is a corresponding edge point in the scene.

15 Through processing all the points, two numbers can be measured: the number of edge points that verified positive (i.e., aligned or matched), and number of points that verified negative (i.e., did not align or did not match). These numbers may be used to compute a “score,” which represents a similarity measure between the potential pattern edges and the pattern edges at given point and angle. For example: if the number of positive edge points (Np) is 1000, and the number of negative edge points (Nn) is 100, the “score” may be determined as:

$$Score = \frac{Np}{Np + Nn}$$

20 In the example, the score is .0909, or 90.9%. The score may be used to determine whether or not the potential reference point is satisfactory.

25 It should be noted that the present invention may be implemented using an image capture device, such as a digital camera, as well as a processor. An example of a suitable processor is a

Pentium®-series processor, manufactured by Intel, Inc., Santa Clara, California. In another embodiment, an application-specific integrated circuit (ASIC) may be used. In still another embodiment, a digital signal processor (DSP) may be used. Other processor types may be used as desired.

EXAMPLE

In order to better understand the present invention, an example is provided. This example does not limit the present invention in any way, and is intended to illustrate one embodiment of the present invention.

The example may be understood by referring to Figs. 7-12. Fig. 7 depicts a pattern that is to be trained; specifically, this figure includes sample shutter part 702. Referring to Fig. 8, shutter 702 has reference point 802, as well as index points 804, 806, 808, 810, 812, and 814. Each index point i ($x0_i, y0_i$) has a front point ($x2_i, y2_i$) and a back point ($x1_i, y1_i$), which are each connected by a stick vector.

If the coordinates for reference point 802 are $x_c = 284$ and $y_c = 192$, then the coordinates of the index points i , with their respective back points and front points, are:

The points		back points		front points	
$x0_i :=$	$y0_i :=$	$x1_i :=$	$y1_i :=$	$x2_i :=$	$y2_i :=$
211.51	198.79	209.60	214.65	226.55	193.37
272.20	255.50	287.68	257.52	257.44	251.46
310.51	252.06	315.91	240.71	295.49	258.13
315.12	196.70	314.50	186.36	318.16	211.00
337.74	143.04	326.81	129.85	338.54	156.32
271.44	164.44	262.71	174.34	280.55	151.78

These points are plotted in the graph of Fig. 9, with the index points plotted as “x” and the back and front points plotted as “o.”

Next, the angle of each stick vector with respect to the x-axis, θ_0 , for each point, i , is determined. This may be determined by the following equation:

$$\Theta_{0i} = \arctan^2[x2_i - x1_i, (y2_i - y1_i) - 1]$$

Thus, for each stick vector, the angle θ_0 is:

$$\theta_0 = \begin{bmatrix} 0.898 \\ 2.944 \\ -2.435 \\ -1.423 \\ -1.154 \\ 0.902 \end{bmatrix}$$

The vector angle of the R vector, θ_1 , for each index point i may be determined by the following equation:

$$\Theta_{1i} = \arctan[x0_i - xc, -(y0_i - yc)]$$

Thus, the resulting angles are:

$$\theta_1 = \begin{bmatrix} -3.048 \\ -1.755 \\ -1.155 \\ -0.15 \\ 0.739 \\ 1.998 \end{bmatrix}$$

The magnitude of the R vector, r , at point with index i may be determined by the following equation:

$$r_i := \sqrt{(x_c - x_{0_i})^2 + (y_c - y_{0_i})^2}$$

The angle difference $\delta\theta$ (the SR Angle) for each index point i is then determined by subtracting θ_1 from θ_0 :

$$\delta\theta = \begin{bmatrix} -3.946 \\ -4.698 \\ 1.28 \\ 1.273 \\ 1.893 \\ 1.097 \end{bmatrix}$$

Next, angle θ_2 for each index point i is determined by the equation:

$$\Theta_{2i} = \arctan[x_{2i} - x_{0_i}, -(y_{2i} - y_{0_i})]$$

Next, the contour curvature, h , for each point, i , is determined.

$$h_i := \sqrt{(x_{2i} - x_{0_i})^2 + (y_{2i} - y_{0_i})^2} \cdot \sin(\alpha_i)$$

Where $\alpha_i = \theta_1 - \theta_2$.

Thus, the values of h are:

$$h = \begin{bmatrix} 8.387 \\ 1.061 \\ 5.13 \\ -0.906 \\ 4.649 \\ -0.707 \end{bmatrix}$$

After these computations, the reference table is created. For the example, the reference table is:

$$h = \begin{bmatrix} 8.387 \\ 1.061 \\ 5.13 \\ -0.906 \\ 4.649 \\ -0.707 \end{bmatrix} \quad r = \begin{bmatrix} 72.807 \\ 64.587 \\ 65.65 \\ 31.473 \\ 72.698 \\ 30.287 \end{bmatrix} \quad \theta_0 = \begin{bmatrix} 0.898 \\ 2.944 \\ -2.435 \\ -1.423 \\ -1.154 \\ 0.902 \end{bmatrix} \quad \theta = \begin{bmatrix} -3.946 \\ -4.698 \\ 1.28 \\ 1.273 \\ 1.893 \\ 1.097 \end{bmatrix}$$

In order to aid in the description of the search process, and to avoid confusion, a subscript r will be added to variables h and θ_0 in the search procedure.

Referring to **Fig. 10**, a scene image is provided. In the same manner described above, the contours are extracted and processed. As an example, several edge points have been selected to show computations in detail. For **Fig. 10**, the coordinates of the index points i , with their respective back points and front points, are:

$x0_i :=$	$y0_i :=$	$x1_i :=$	$y1_i :=$	$x2_i :=$	$y2_i :=$
454.44	320.86	459.39	306.41	439.14	325.28
404.46	256.85	389.00	251.44	417.90	262.40
365.49	253.50	358.95	264.30	381.54	249.97
353.11	307.43	352.36	318.21	352.21	293.48
321.81	357.01	331.54	370.95	324.09	343.99
390.35	345.81	400.95	338.31	380.08	357.62

These points are plotted in the graph of **Fig. 11**, with the index points plotted as “x” and the back points plotted as “o.”

Next, the angle of each stick vector with respect to the x-axis, θ_0 , the angle θ_2 , and the contour curvature hr for each point, i , is determined in the same manner described above. Thus, the stick vector angles θ_0 and the contour curvatures hr are:

$$\theta_0 = \begin{matrix} -2.391 \\ -0.362 \\ 0.565 \\ 1.577 \\ 1.84 \\ -2.395 \end{matrix} \quad hr = \begin{matrix} 8.837 \\ 1.061 \\ 5.13 \\ -0.906 \\ 4.649 \\ -0.707 \end{matrix}$$

Next, the potential reference point is calculated. First, for points with a contour curvature above ± 7 , only one point exists at $i = 0$. Thus, the potential reference point and angle of rotation are calculated for this point:

$$\begin{aligned} \theta_{1_0} &:= \theta_{0_0} + \theta_{0_0} \\ xc_{found_0} &:= x_{0_0} - r_0 \cdot \cos(\theta_{1_0}) & xc_{found_0} &= 381.741 \\ yc_{found_0} &:= y_{0_0} + r_0 \cdot \sin(\theta_{1_0}) & yc_{found_0} &= 316.883 \\ rotAngle_0 &:= \theta_{0_0} - \theta_{0_0} & rotAngle_0 &= 3.29 \end{aligned}$$

For points with a contour curvature above about ± 5 , two points exist at $i = 2$ and $i = 4$. Thus, the potential reference point and angle of rotation are calculated for these points:

$$\begin{aligned} \theta_{1_2} &:= \theta_{0_2} + \theta_{0_2} \\ xc_{found_2} &:= x_{0_2} - r_2 \cdot \cos(\theta_{1_2}) & xc_{found_2} &= 383.297 \\ yc_{found_2} &:= y_{0_2} + r_2 \cdot \sin(\theta_{1_2}) & yc_{found_2} &= 316.689 \\ rotAngle_2 &:= \theta_{0_2} - \theta_{0_2} & rotAngle_2 &= -3.001 \\ \theta_{1_4} &:= \theta_{0_4} + \theta_{0_4} \\ xc_{found_4} &:= x_{0_4} - r_4 \cdot \cos(\theta_{1_4}) & xc_{found_4} &= 382.163 \\ yc_{found_4} &:= y_{0_4} + r_4 \cdot \sin(\theta_{1_4}) & yc_{found_4} &= 316.481 \\ rotAngle_4 &:= \theta_{0_4} - \theta_{0_4} & rotAngle_4 &= -2.994 \end{aligned}$$

For points with a contour curvature of about ± 1 , three points exist at $i = 1$, $i = 3$, and $i = 5$. Thus, the potential reference point and angle of rotation are calculated for these points:

$$\begin{aligned}\theta_{1_1} &:= \theta_{0_1} + \theta_{\theta_1} \\ \text{xcfound}_1 &:= x_{0_1} - r_1 \cdot \cos(\theta_{1_1}) & \text{xcfound}_1 &= 382.408 \\ \text{ycfound}_1 &:= y_{0_1} + r_1 \cdot \sin(\theta_{1_1}) & \text{ycfound}_1 &= 317.556 \\ \text{rotAngle}_1 &:= \theta_{0_1} - \theta_{1_1} & \text{rotAngle}_1 &= 3.306\end{aligned}$$
$$\begin{aligned}\theta_{1_5} &:= \theta_{0_5} + \theta_{\theta_5} \\ \text{xcfound}_5 &:= x_{0_5} - r_5 \cdot \cos(\theta_{1_5}) & \text{xcfound}_5 &= 382.199 \\ \text{ycfound}_5 &:= y_{0_5} + r_5 \cdot \sin(\theta_{1_5}) & \text{ycfound}_5 &= 316.64 \\ \text{rotAngle}_5 &:= \theta_{0_5} - \theta_{1_5} & \text{rotAngle}_5 &= 3.297\end{aligned}$$
$$\begin{aligned}\theta_{1_3} &:= \theta_{0_3} + \theta_{\theta_3} \\ \text{xcfound}_3 &:= x_{0_3} - r_3 \cdot \cos(\theta_{1_3}) & \text{xcfound}_3 &= 383.257 \\ \text{ycfound}_3 &:= y_{0_3} + r_3 \cdot \sin(\theta_{1_3}) & \text{ycfound}_3 &= 316.469 \\ \text{rotAngle}_3 &:= \theta_{0_3} - \theta_{1_3} & \text{rotAngle}_3 &= -3\end{aligned}$$

After these calculations, the potential reference points (xcfound_i, ycfound_i) are added to an accumulator. Referring to **Fig. 12**, an image of the accumulator is provided. For the angles of rotation, the same process is repeated.

The results of the computation show that the potential reference point is about (383, 317) and at an angle of about 3.1 radians. These results coincide with the actual reference point location, which is (383,318) and an angle of $318.94 = 3.298$ radians.

While the invention has been particularly shown and described by the foregoing detailed description, it will be understood by those skilled in the art that various other changes in form and detail may be made without departing from the spirit and scope of the invention.

WHAT IS CLAIMED IS:

1. A method for locating a pattern, comprising:

providing a pattern image corresponding to the pattern to be located;

5 extracting at least one pattern contour from the pattern image;

generating vector information for each of said at least one pattern contours, relative to a reference point;

creating at least one reference table for storing the vector information, each of said at least one reference tables corresponding to said at least one pattern contour;

10 providing a scene image, which will be searched for the pattern;

extracting at least one scene contour from the scene image;

generating vector information for each of said at least one scene contours; and

15 determining whether the pattern has been located within the scene image using the at least one reference tables and the vector information for the at least one scene contours, and if so, identifying a location of the pattern within the scene image and an angle of rotation of the pattern within the scene image.

2. The method of claim 1, wherein the step of extracting at least one pattern contour from the pattern image comprises:

20 locating at least one edge in the pattern image;

recording a starting point for the at least one edge;

crawling along the at least one edge of the pattern image;

extracting a plurality of pixels from the at least one edge, beginning with the starting point and continuing with pixels identified while crawling along the at least one edge;

25 filtering the plurality of extracted pixels; and

creating a pattern contour from the plurality of extracted pixels.

3. The method of claim 1, wherein the step of extracting at least one pattern contour from a pattern image comprises:

30 extracting at least one pattern contour from the pattern image;

identifying undetected edge points; and

modifying the at least one pattern contour to add any undetected edge points.

4. The method of claim 3, wherein the step of extracting at least one pattern contour from a pattern image further comprises:

removing aliased edge points from the at least one pattern contour;

spatially filtering the pattern contours; and

resampling the filtered pattern contours.

5. The method of claim 1, wherein the step of generating vector information for each of said at least one pattern contours comprises:

selecting a reference point for each of said at least one pattern contours; and

generating vector information for each of said at least one pattern contours, relative to the selected reference point.

6. The method of claim 1, wherein the step of generating vector information for each of said at least one pattern contours, relative to the selected reference point, comprises:

choosing an index point corresponding to a point along said at least one pattern contour;

establishing a front point and a back point for said index point, the front point and the back point defining a stick vector;

establishing a R vector from the index point to the selected reference point;

determining a contour curvature value for the index point, the contour curvature value being a shortest distance between the index point and the stick vector;

determining a stick angle, the stick angle being an angle between the stick and the horizontal axis; and

determining a SR angle for the index point, said SR angle being the angle between the stick vector and the R vector.

7. The method of claim 6, wherein a plurality of index points are chosen, and contour curvature values and SR angles are calculated, respectively, for each of said plurality of index

points.

8. The method of claim 7, wherein the step of generating vector information for each of said at least one pattern contours, relative to the selected reference point, further comprises:

for each index point of said plurality of index points, determining a GR angle between a gradient of each of said index points and the respective R vectors for said index points.

9. The method of claim 6, wherein the step of creating at least one reference table containing said vector information comprises:

grouping the SR angles based on a contour curvature value;
grouping the stick angles based on the contour curvature value; and
grouping the R vector information based on the contour curvature value.

10. The method of claim 9, wherein the step of creating at least one reference table containing said vector information further comprises:

grouping the GR angles based on the contour curvature value at the index point.

11. The method of claim 6, wherein the SR angle is rotation invariant.

12. The method of claim 1, wherein the step of extracting at least one scene contour from a scene image comprises:

locating at least one edge in the scene image;
recording a starting point for the at least one edge of the scene image;
crawling along the at least one edge of the scene image;
extracting a plurality of pixels from the at least one edge, beginning with the starting point and continuing with pixels identified while crawling along the at least one edge of the scene image;
filtering the plurality of extracted pixels; and
creating a scene contour from the plurality of extracted pixels.

13. The method of claim 1, wherein the step of generating vector information for each of said at least one scene contours comprises:

choosing at least one scene index point corresponding a point along said at least one scene contour;

determining a scene stick angle, the scene stick angle being an angle between a scene stick and the horizontal axis; and

determining a scene contour curvature and a scene SR angle for each of said at least one scene index points.

14. The method of claim 13, wherein the step of generating vector information for each of said at least one scene contours further comprises:

determining a scene GR angle for each of said at least one scene index points.

15. The method of claim 1, wherein the step of determining whether the pattern has been located comprises:

calculating at least one potential reference point based on the extracted scene contour vector information and recording the instance of each of said at least one potential reference points;

calculating at least one potential angle of rotation based on the extracted scene contour vector information and recording the instance of each of said at least one potential angles of rotation;

identifying a location of the pattern within the scene image using the recorded potential reference points; and

determining an angle of rotation for the pattern within the scene image using the recorded potential angles of rotation.

16. The method of claim 15, wherein the step of calculating at least one potential reference point comprises:

calculating a potential reference point for each point in the reference table.

17. The method of claim 16, wherein the potential reference point is calculated from the SR angles and the vector information.

18. The method of claim 15, wherein the step of calculating at least one potential reference point based on the extracted scene contour vector information and recording the instance of each of said at least one potential reference points comprises:

adding the potential reference point to a reference point accumulator.

19. The method of claim 15, wherein the step of calculating at least one potential angle of rotation based on the extracted scene contour vector information and recording the instance of each potential angle of rotation comprises:

determining an angle difference between the scene stick angle and the stick angle in the reference table; and

adding the potential angle of rotation to an angle accumulator.

20. The method of claim 15, wherein the step of determining an angle of rotation for the pattern image comprises:

clustering the potential angles of rotation; and

identifying at least one potential angle of rotation where clustering has occurred beyond a predetermined threshold.

21. A method for pattern recognition, comprising:

extracting pattern vector information from at least one pattern image, each pattern image having a pattern reference point;

creating a reference table containing the pattern vector information for each of the at least one pattern image;

extracting scene contour information from a scene image;

calculating a potential reference point based on the scene contour information and the reference table;

matching the potential reference point with one of the at least one pattern reference

points; and

identifying a pattern image corresponding to the matching pattern reference point.

22. The method of claim 21, further comprising:

identifying an angle of rotation for the scene image.

23. The method of claim 21, wherein the pattern vector information includes a rotation invariant angle.

24. The method of claim 23, wherein the rotation invariant angle is defined by:

identifying at least one pattern index point on a contour of the pattern image;

identifying a front point and a back point for the pattern index point, the front point and back point defining a stick vector; and

identifying a R vector defined by the index point and the pattern reference point;

wherein the rotation invariable angle is defined by a SR angle between the stick vector and the R vector.

25. The method of claim 21, wherein the step of calculating a potential reference point based on the scene contour information and the reference table comprises:

identifying at least one scene index point on a contour of the scene image;

calculating the potential reference point for each of the scene index points based on the reference table;

adding the potential reference point to a reference point accumulator; and

determining a likely potential reference point.

26. A system for pattern identification, comprising:

a first image capture device that captures a pattern image, the pattern image including an image of a pattern;

a second image capture device that captures a scene image to be searched for the pattern;

a processor for processing the pattern image and the scene image, the processor

comprising:

means for extracting at least one pattern contour from the pattern image;

means for generating vector information for each of said at least one pattern contours, relative to a reference point;

means for creating at least one reference table for storing vector information, each of said at least one reference tables corresponding to at least one pattern contour;

means for extracting at least one scene contour from a scene image;

means for generating vector information for each of said at least one scene contours; and

means for locating the pattern image within the scene image using the at least one reference table and the vector information for the at least one scene contours.

27. The system of claim 26, further comprising:

a database for storing the at least one reference table.

28. The system of claim 27, wherein the database stores at least one reference table for a plurality of pattern images.

29. The system of claim 26, wherein the first image capture device and the second image capture device comprise a common image capture device.

SYSTEM AND METHOD FOR PATTERN IDENTIFICATION

ABSTRACT OF THE DISCLOSURE

5 A system and method for pattern identification are disclosed. According to one embodiment of the present invention, the method for locating a pattern includes the steps of (1) providing a pattern image corresponding to the pattern to be located; (2) extracting a pattern contour from the pattern image; (3) generating vector information for the pattern contours, relative to a reference point; (4) creating a reference table for storing the vector information, the reference tables corresponding to the pattern contour; (5) providing a scene image, which will be searched for the pattern; (6) extracting a scene contour from the scene image; (7) generating vector information for the scene contours; and (8) determining whether the pattern has been located within the scene image using the reference table and the vector information for the scene contour. According to another embodiment, a system includes a first image capture device that captures a pattern image which includes an image of a pattern; a second image capture device that captures a scene image to be searched for the pattern; a processor for processing the images, which includes means for extracting at least one pattern contour from the pattern image; means for generating vector information for each of said at least one pattern contours, relative to a reference point; means for creating at least one reference table for storing vector information, each of said at least one reference tables corresponding to at least one pattern contour; means for extracting at least one scene contour from a scene image; means for generating vector information for each of said at least one scene contours; and a means for locating the pattern image within the scene image using the at least one reference tables and the vector information for the at least one scene contours.

DECLARATION AND POWER OF ATTORNEY FOR PATENT APPLICATION

As the below named inventor, I hereby declare that:

My residence, post office address and citizenship is as stated below next to my name;

I believe that I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

SYSTEM AND METHOD FOR PATTERN IDENTIFICATION

the specification of which: ☒ is attached hereto.
☐ was filed on: _____
as Application No.: _____
and was amended on _____ (if applicable).

I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above. I acknowledge the duty to disclose information which is material to patentability as defined in 37 C.F.R. § 1.56.

Prior Foreign Application(s)

I hereby claim foreign priority benefits under Title 35, United States Code, § 119(a)-(d) or § 365(b) of any foreign application(s) for patent or inventor's certificate, or § 365(a) of any PCT international application which designated at least one country other than the United States of America, listed below and have also identified below any foreign application(s) for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

Country	Application Number	Date of Filing (day, month, year)	Date of Issue (day, month, year)	Priority Claimed	
N/A				Yes <input type="checkbox"/>	No <input type="checkbox"/>
				Yes <input type="checkbox"/>	No <input type="checkbox"/>
				Yes <input type="checkbox"/>	No <input type="checkbox"/>

Prior Provisional Application(s)

I hereby claim the benefit under Title 35, United States Code § 119(e) of any United States provisional application(s) listed below:

Application Number	Date of Filing (day, month, year)
N/A	

Prior United States Application(s)

I hereby claim the benefit under Title 35, United States Code, § 120 of any United States application(s), or § 365(c) of any PCT international application designating the United States of

America, listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, § 112, I acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, § 1.56(a) which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

Application Number	Date of Filing (day, month, year)	Status - Patented, Pending, Abandoned
N/A		

And I hereby appoint, both jointly and severally, as my attorneys with full power of substitution and revocation, to prosecute this application and to transact all business in the Patent and Trademark Office connected herewith the following attorneys, their registration numbers being listed after their names:

Rodger L. Tate, Registration No. 27,399; Anthony W. Shaw, Registration No. 30,104; James Remenick, Registration No. 36,902; Michael J. Songer, Reg. No. 39,841; Cono A. Carrano, Registration No. 39,623; Laurence H. Posorske, Registration No. 34,698; Floyd B. Chapman, Registration No. 40,555; David J. Kulik, Registration No. 36,576; Robert A. King, Registration No. 42,738; and Trevor Q. Coddington, Registration No. 46,633.

All correspondence and telephone communications should be addressed to: **Intellectual Property Department; Brobeck, Phleger & Harrison LLP; 1333 H Street, N.W.; Suite 800; Washington, DC 20005**, telephone number (202) 220-6000; facsimile number (202) 220-5200, which is also the address, telephone and facsimile numbers of each of the above listed attorneys.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine and imprisonment, or both, under 18 U.S.C. § 1001, and that such willful false statements may jeopardize the validity of the application or any patent issuing thereon.
